

General:

The equipment is homologated in several countries where the technical requirements are based on the CEPT Recommendation T/R 17.

Frequency range:	146 - 174 MHz
Principle:	Digital frequency synthesizer
Number of channels:	Max. 80
Channel spacing:	25 kHz or 20 kHz
RF-bandwidth:	typ. 2 MHz at 1 dB reduction
Mode of operation:	Simplex, semi-duplex and duplex
Supply voltage:	12 V DC chassis negative - nom. 13,2V. DC-DC converter available for 6V, 24V and 12V chassis positive operation. A 220V AC supply is available too.
Supply voltage variations:	10,8V to 15,6V
Operation Temperature:	-25°C to + 60°C
Frequency stability:	typ. ± 10 ppm for the above specified temperature and supply voltage variations
Loudspeaker:	External 4Ω
Microphone:	1 kΩ condenser microphone or 200Ω dynamic close talk microphone with push-button
Antenna impedance:	50Ω
Power consumption:	At 13,2 V reception approx. 0,25 A · transmission { 25W approx. 5,5A { 6W " 2,0A
<u>Receiver:</u>	
Sensitivity:	typ. 0,4µV ( $\frac{1}{2}$ E.M.F.) for 20 dB SINAD.
Adjacent channel sensitivity:	typ. 75 dB (CEPT Method)
Spurious and image rejection:	typ. 80 dB (CEPT Method)
Intermodulation attenuation:	typ. 71 dB (CEPT Method)
Undesired conducted power:	typ. 0,5 nW
Deemphasis:	Following 6dB per octave curve from 0,3 to 3 KHz within +1-3dB relative level at 1000 Hz

Output for microtelephone:

distortion, 15,6V supply voltage

1mW in  $300\Omega$

Hum and noise:

Typ. 50 dB (CEPT Method)

Function of limiter:

Less than 1dB variation in output voltage for RF-input levels between 1 $\mu$ V and 100 mV EMF

Transmitter:

Power output:

without external PA: 6W  $\pm$  0,5 dB from  $\pm 25^{\circ}\text{C}$  to  $+ 60^{\circ}\text{C}$  and supply voltages between 10,8V and 15,6V

with external PA: 25W + 0dB  $\pm$  2dB from  $\pm 25^{\circ}\text{C}$  to  $+ 60^{\circ}\text{C}$  and supply voltages between 10,8V and 15,6V

typ. each less than 2 $\mu$ W into  $50\Omega$

typ. 85dB below the output power max.  $\pm$  5 kHz

Following 6dB per octave curve from 0,3 to 3 kHz within +1-3dB relative level at 1000 Hz

typ. 1 per cent at  $\pm$  3kHz deviation and 1000 Hz modulation frequency

typ. 50 dB relative  $\pm$  3kHz deviation and 1000 Hz modulation frequency (CEPT Method)

Spurious outputs and harmonics:

Adjacent channel power:

Frequency deviation:

Preemphasis:

Harmonic distortion:

Hum and noise:

Hum and noise:

## Technical description for AP 2000

### RECEIVER (Fig. 1)

#### Aerial switch (75010-4E2 or 75011-4E2)

The aerial switch is made by a relay, while C1, TR1 and D1 makes a forward power sensing circuit for the transmitter. (In a duplex set, the relay is not mounted).

#### RF-amplifier and 1st mixer (75015-4E2)

The RF amplifier consists of a Dual-gate Mos-transistor with several tuned circuits to give the necessary selectivity. The first mixer converts the RF-signal 147 - 174 Mc to 21,4 Mc with an oscillator injection of 168,4 - 195,4 Mc on gate 2. Matching of the mixer output impedance to the crystal filter is made by the turned circuit L 6.

#### 21,4 Mc and 455 kc IF (75076-3E2)

The 21,4 Mc crystal filter is followed by a dual-gate Mos-amplifier which gives approximately 20 dB gain. This stage is followed by the second mixer which converts 21,4 Mc to the low IF 455 kc. The second mixer consists of an integrated doublebalanced transistor mixer, in which one section is used as the crystal oscillator. An emitter follower with some RC low-pass sections feeds the signal to IC 2, which is an integrated high gain amplifier/limiter and quadrature detector. The coil L 4 is the detector phase shift network. AF output is supplied by the emitter follower Q 3.

#### AF-amplifier, squelch and key circuit (75017-3E2)

The AF-signal goes through an amplifier stage Q 6 to the volume control circuit. Here, the diodes D 1, D 2 and D 3 act as an

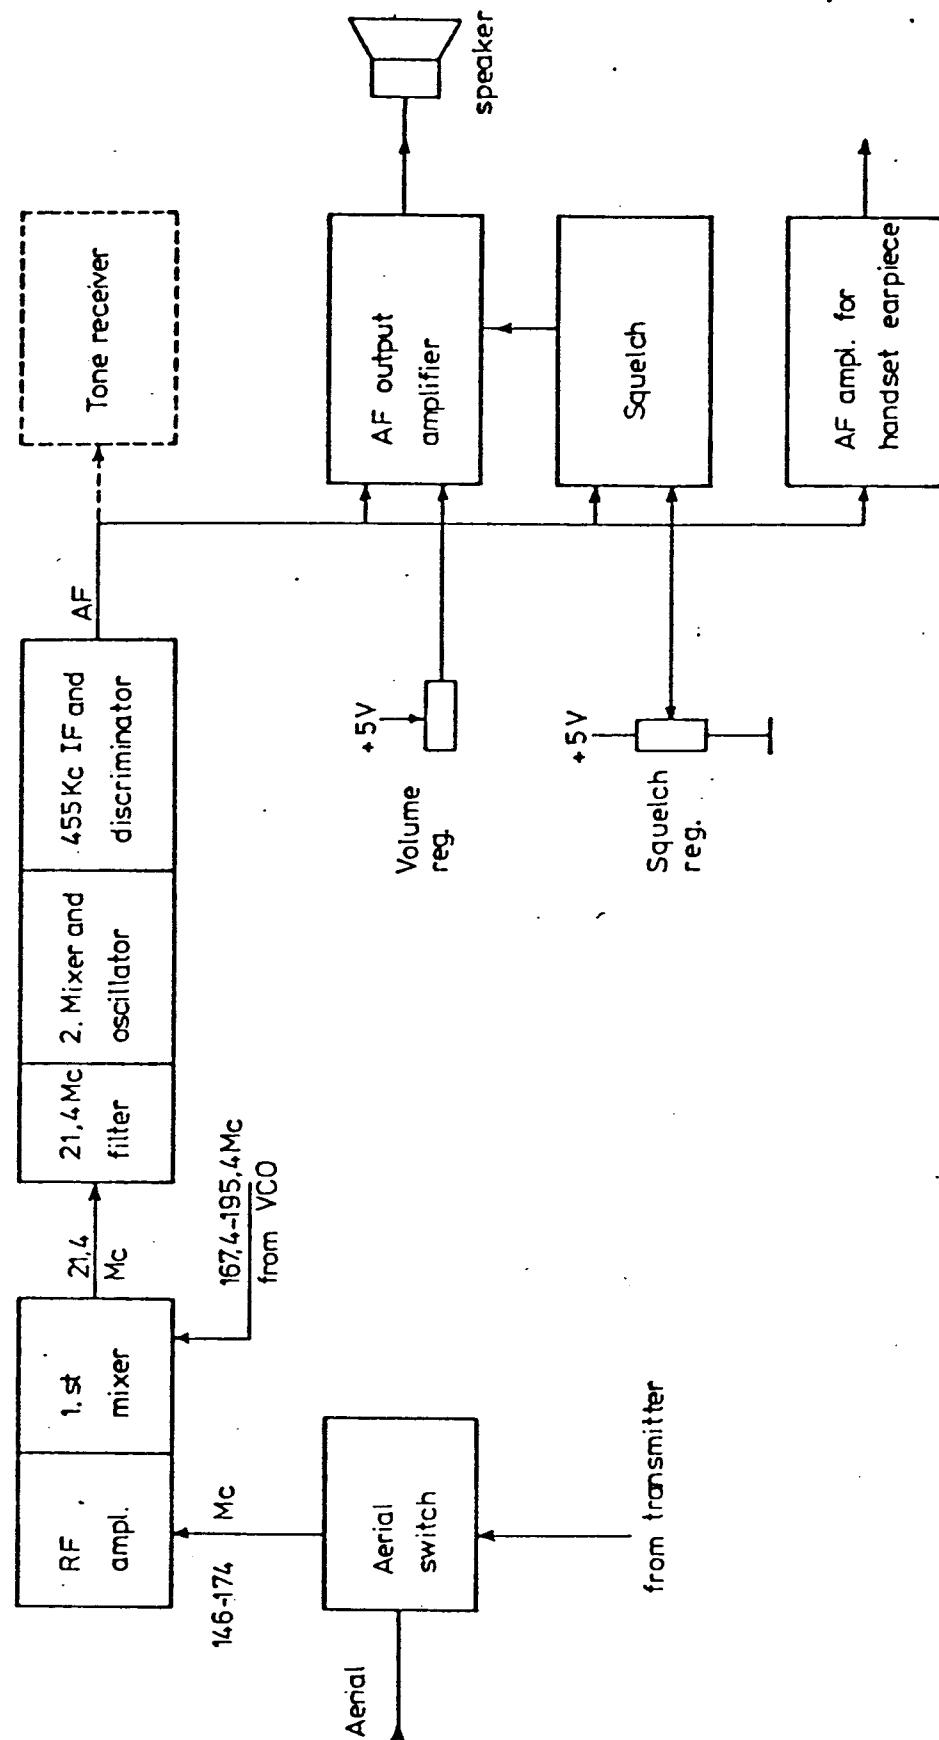

Fig. 1

Rettet:	Tegn.: 30-4-75 AC	Kontr.:
Technical decription for AP 2000, 2m band		
AP-RADIOTELEFON X	Page: 2	Tegn. nr.: 75204-4E2

An integrated AF output amplifier is used for the 5 W 1000-speaker output and here the feedback-capacitors C 6 and C 7 produce the deemphasis.

For the handset earpiece Q 4 and Q 5 makes an amplifier while D 15 is for blocking. The squelch circuit consists of an 8 kc tuned amplifier Q 3 followed by a detector D 11 and D 12. With increasing noise level on the AF-input the voltage on the negative side on C 19 will decrease from + 5 V. Getting lower than the squelch reg. voltage on point 7, the amplifier IC 2 switches over to an output voltage of + 5 V and thus blocking the AF-output through the volume control circuit.

In the key control circuit Q 1 and Q 2 goes ON when the button in the handset connects point 11 to chassis, thus producing + 12 V on point 14. A positive voltage applied on point 10 will inhibit this function.

#### TRANSMITTER (Fig. 2)

##### Transmitter mixer and amplifier (75014-4E2)

Because the VCO has a frequency 21,4-Mc higher than the operating RX-frequency this signal is fed to the transmitter mixer and converted to the desired transmitting frequency. For simplex operation the necessary 21,4 Mc signal comes from a combined crystal oscillator/doubler. Thus the crystal will be 10,7 Mc. For good suppression of VCO - and 21,4 Mc injection the TX-mixer is a balanced diode type. The three amplifier stages Q 1, Q 2 and Q 3 give further suppression of unwanted sidebands and the necessary amplification to reach an output of approx. 150 mW.

##### 6 W power amplifier (75013-4E2)

The 6 W power amplifier consists of two stages Q 1 and Q 2, where the output level can be regulated by varying the supply voltage for Q 1.

##### 25 W PA-stage (75009-4E2)

The output from the 25 W PA-stage goes through a forward power-

Tegn. nr.: 75204-4E2

### Output power stabilizing 75622-4E2 and 76325-4E2

From the power-sensing circuit a DC voltage proportional to the forward power is led to an amplifier. Here it is compared to a zener-voltage, and if it is greater than this threshold level, the amplifier IC 1 will give less base-current for Q 1, and thus reduce the voltage for driver transistor Q 1 in the 6 W stage. This will act in the following manner:

For low supply voltages ( $\sim 11$  V) the output power will increase with increasing supply voltage, and when the output reaches 25 W it will be constant for further increase in supply voltage. The output level for supply voltage greater than approx. 13 V is adjustable with R 1. Note that the oscillator for TX-mixer, the transmitter mixer and amplifier, and sense amplifier have keyed supply lines, while the final transistor in the 6 W stage and the 25 W stage are supplied independent of the key. If external PA is used R1 is located in there.

### Aerial filter (75016-4E2)

The aerial filter is a low-pass filter for suppression of the harmonics from the transmitter.

### Modulation amplifier (75018-3E2)

The modulation amplifier has a preamplifier Q 1 for the most sensitive input (input 1). Using the less sensitive input 2, the Mic. switch terminal shall have + 5 V so that Q 1 will be blocked via D 3 and D 4 will be conducting for the input signal to IC 1. For selective tone transmission the tone TX input is used while Q 1 is blocked via D 2. D 5 is used for blocking of the modulation amplifier while receiving in simplex mode. IC 1 and the first part of IC 2 work as a compressor/amplifier to limit the maximum output AF-voltage. When using a variable gain type amplifier as IC 1 it is possible to avoid the distortion for high AF-levels, which occurs in a conventional clipper-circuit. The other amplifier in IC 2 is used as a 3 kc active low-pass filter. A tuning diode in the VCO is used for modulation.

Basic phase lock loop operation

A simple phase locked loop consists of 3 elements, a phase comparator, a filter and the VCO (Fig. 3).

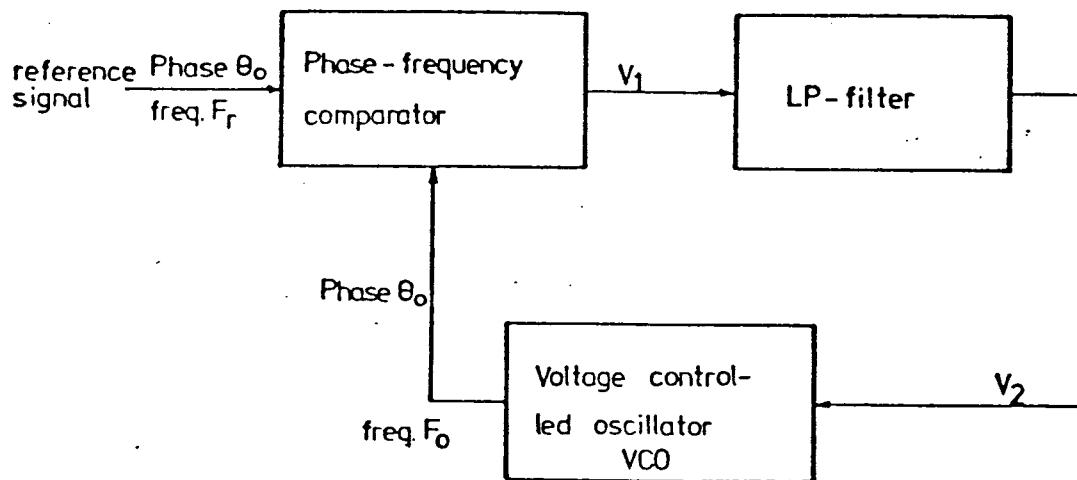

Fig. 3      Basic phase locked loop.

Phase-frequency comparator

If the VCO-frequency  $F_o = F_r$ , the comparator gives out a DC-level proportional to the phase difference between  $F_o$  and  $F_r$  (Fig. 4). We have  $V_1 = K_1 \times (\theta_r - \theta_o)$  where  $K_1$  is a constant. When there is a frequency difference between  $F_o$  and  $F_r$ ,  $V_1$  will be low for  $F_o$  greater than  $F_r$  and high for  $F_o$  less than  $F_r$ .

Voltage controlled oscillator

This can be a LC-oscillator whose frequency is controlled with a varicap.  $F_o = K_2 \times V_1$  where  $K_2$  is a constant.

LP-filter

This filter removes the ripple on  $V_1$  (Fig. 4) and determines the dynamic behaviour (stability, step response) of the loop.

Let us consider a situation where the loop is out of lock and

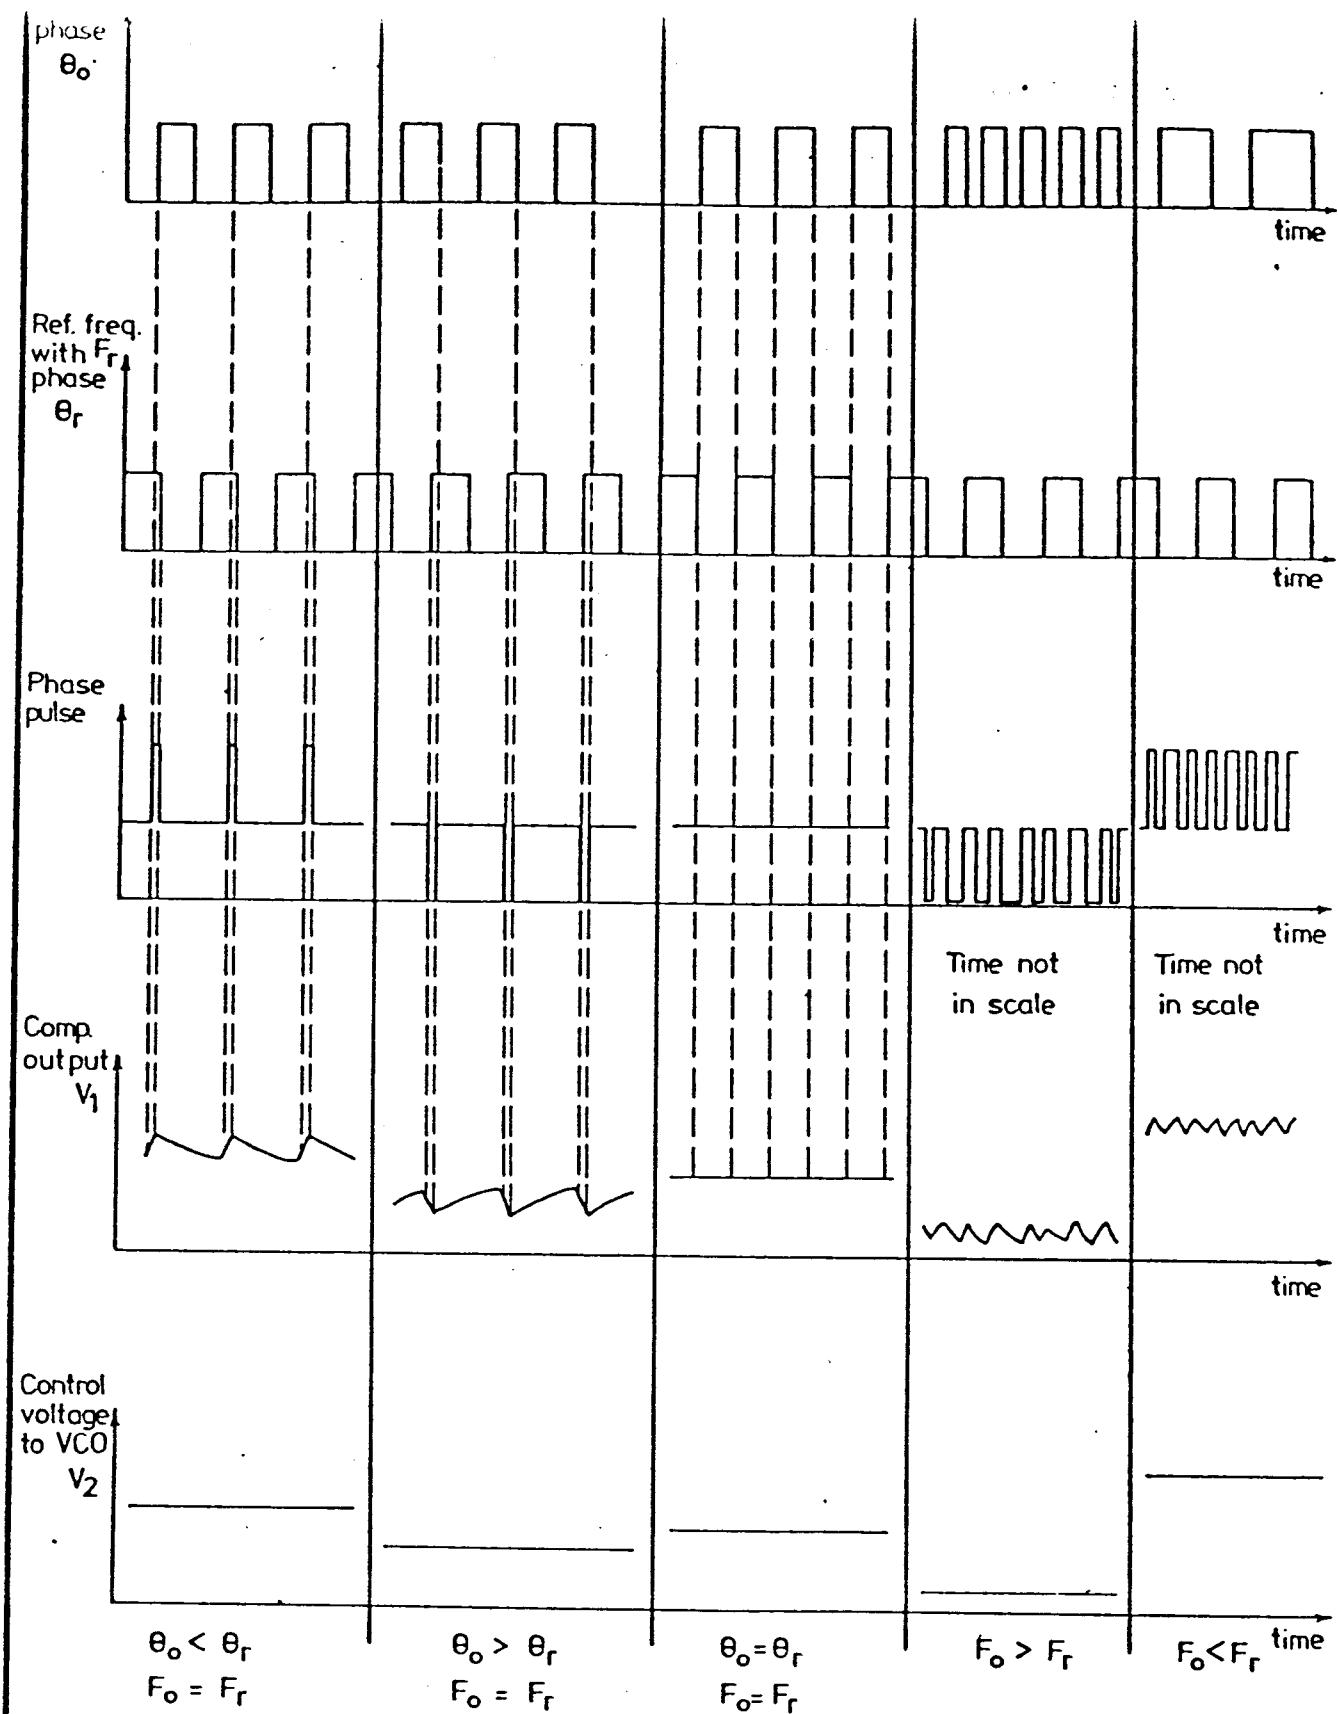

Fig. 4

Rettet:	Figure for synthesizer description	Tegn.: 13-5-75	Kontr.:
		AC	
AP-RADIOTELEFON %		Page: 7	
		Tegn. nr.:	75204-4E2

$F_o$  is greater than  $F_r$ . The comparator output voltage  $V_1$  will contain the normal ripple with frequency  $F_r$  and a beat note, but the mean DC level ( $= V_2$  after the filter) will be low (Fig. 4). Thus the VCO frequency will decrease and at the time  $F_o$  reaches  $F_r$  the loop will go in lock. Now  $F_o = F_r$  and the phase difference will assume a level for  $V_2$  sufficient to hold the VCO frequency in lock with  $F_r$ . If the tuning of the VCO is changed (such as by varying the value of the tuning capacitor) the frequency  $F_o$  from the VCO will attempt to change. This will result in a change in phase angle between  $F_o$  and  $F_r$ , resulting in a change in DC-level of  $V_1$  which will act to maintain frequency lock. In this way tuning of the VCO will change the ripple and the DC-level on  $V_1$  but as long as lock is maintained  $F_o$  will be equal  $F_r$ .

A multichannel synthesizer (Fig. 5)

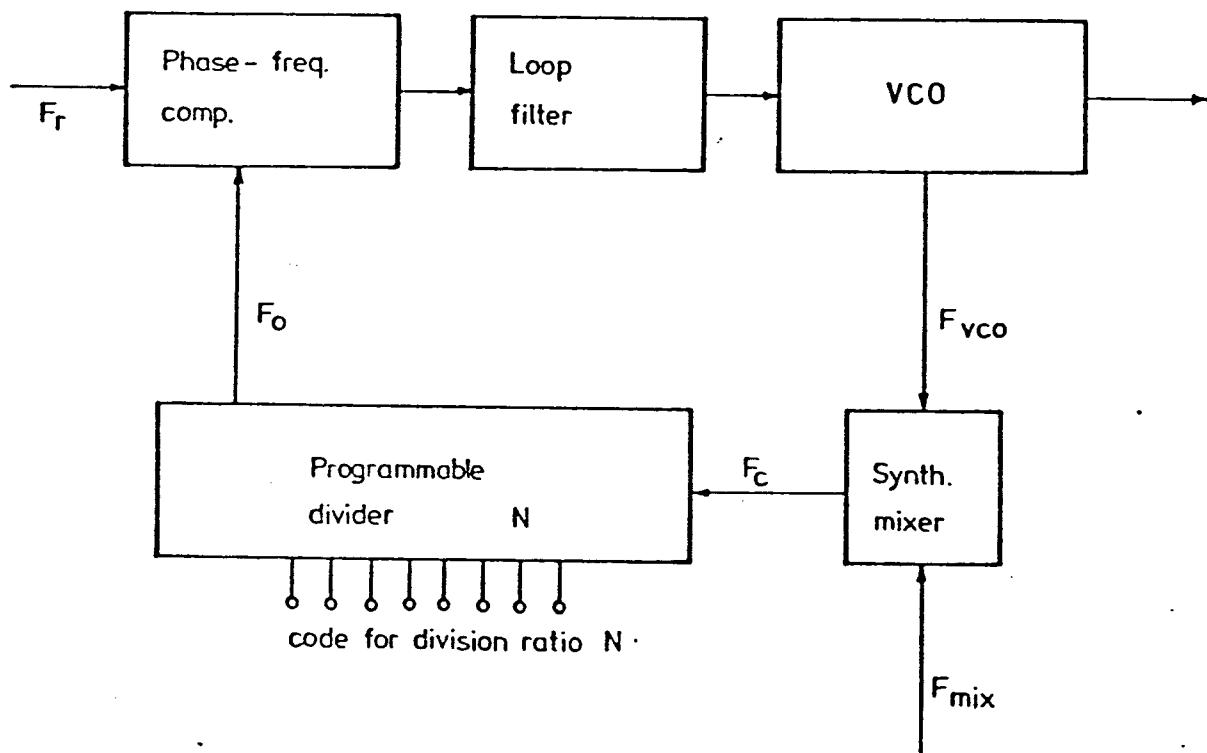

Fig. 5      Synthesizer loop

To build a multichannel synthesizer we have to add some more components (Fig. 5) but the basic function is the same. Here the VCO frequency is converted to a lower frequency  $F_c$  suitable

for the digital divider.  $F_c = F_{vco} - F_{mix}$  (1). When the loop is in lock the incoming frequencies  $F_r$  and  $F_o$  are equal, but they can have a phase difference.  $F_o = F_r$  (2). The programmable divider divides frequency  $F_c$  with a number N, which can be selected by a binary code.  $F_c = N \times F_o$  (3).

Combining equations (1), (2) and (3) give

$$F_{vco} = F_{mix} + N \times F_r \quad (4).$$

By changing the division ratio N we can get a lot of VCO-frequencies with the spacing  $F_r$ , and the stability depends only on  $F_{mix}$  and  $F_r$  which can be crystal oscillators.

#### The synthesizer circuit in AP 2000 (Fig. 6)

##### Synthesizer logic (75062-3E2)

The 25 kc reference frequency is produced by dividing a 400 kc crystal oscillator (X 1 and Q 4) by 16 in the counter IC 6.

The input signal to the programmable divider is amplified in Q 1 and Q 2, while the two gates from IC 1 shape the waveform to narrow pulses. IC 2 and IC 3 form the programmable divider, where the division ratio N is the Binary number on the eight channel code lines. The numbers on the code lines correspond to the binary value of each line. In this way a division ratio  $N = 168$  will have a channel code:

Number on code line	128	64	32	16	8	4	2	1
Binary value	128	64	32	16	8	4	2	1
Code for $N = 168$	1	0	1	0	1	0	0	0

where 0 means OV and 1 means + 5 V.

- The two cascaded counters IC 2 and IC 3 count down from 168. When the counters reach zero a borrow pulse is generated and used to preset the number 168, thus starting a new count cycle. The very narrow borrow pulses with a repetition rate of 25 kc are used as input to the frequency-phase comparator IC 4. The comparator output voltage  $V_1$  (Fig. 2) can be seen on a test point TP 1. To suppress the 25 kc ripple on the comparator output voltage Q 3 is connected as an active lowpass filter. IC 5 is for DC-amplification.

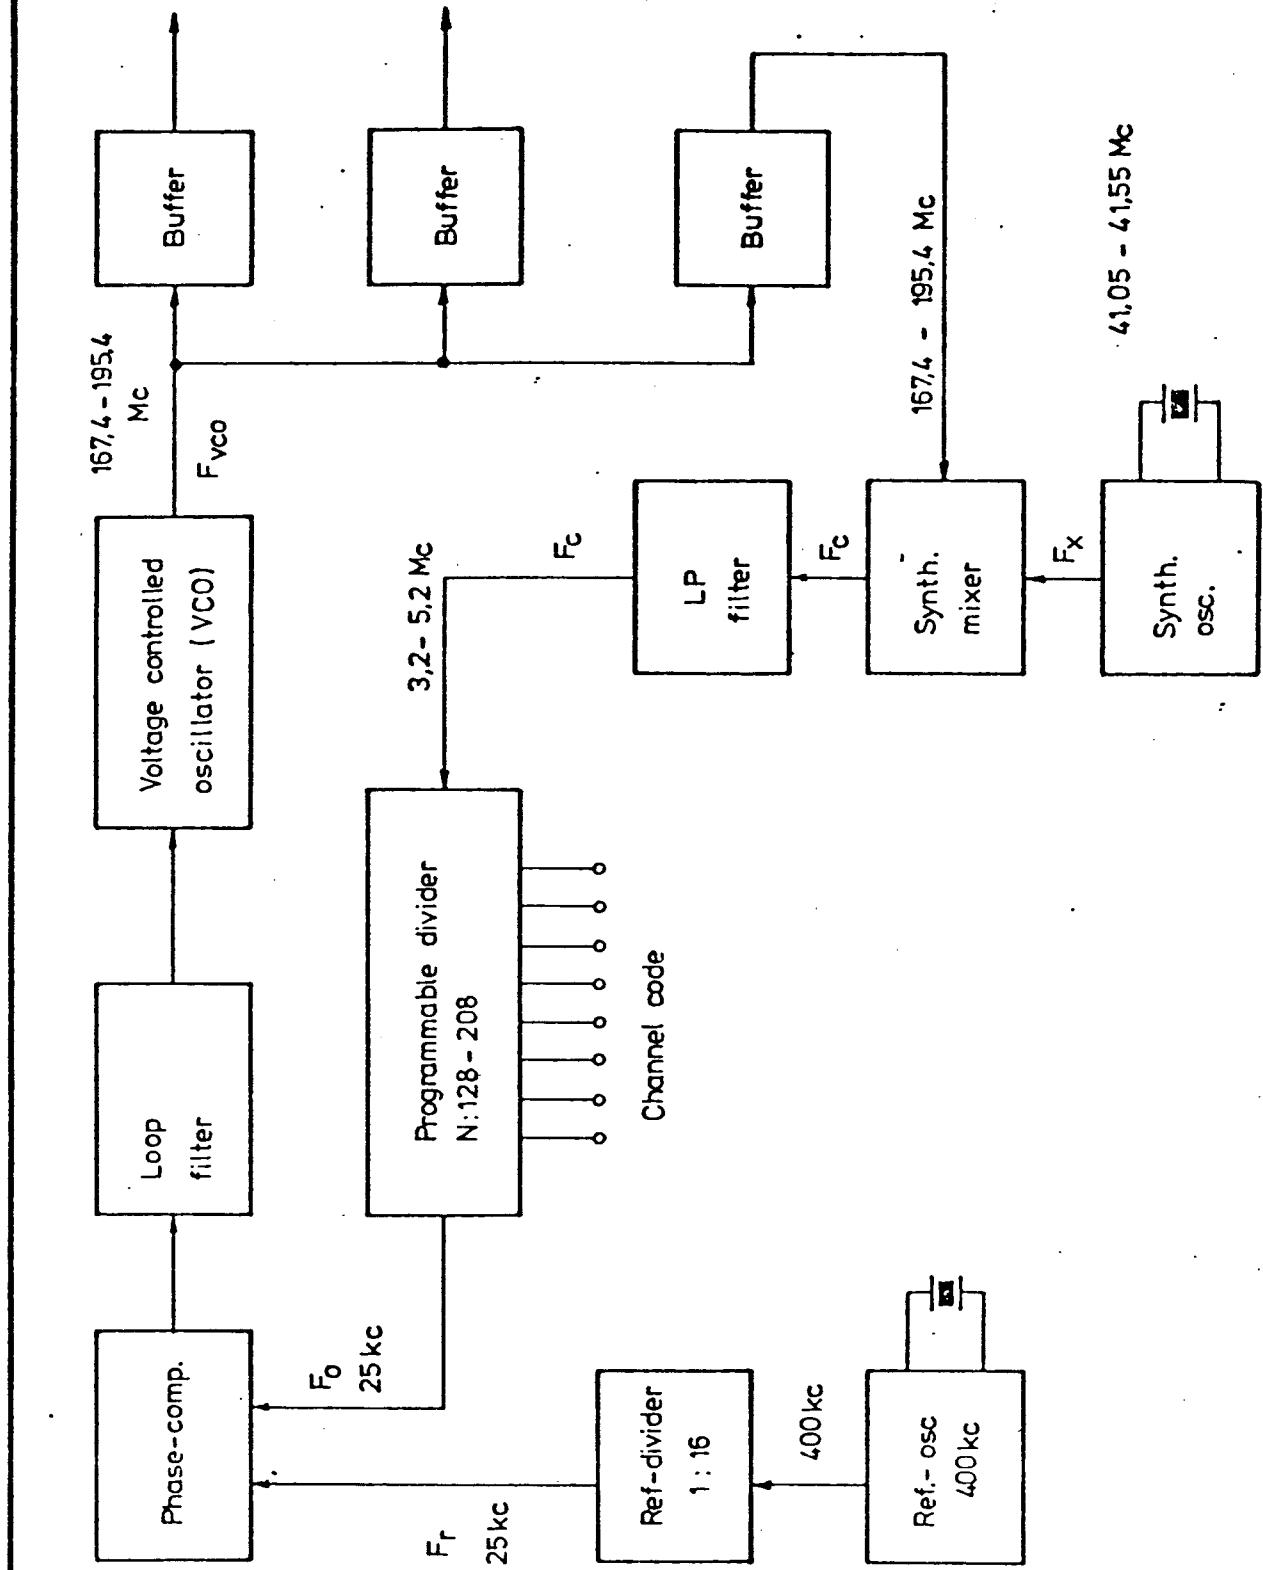

Fig 6

Rettet:	Tegn.:13-5-75 AC		Kontr.:
Figure for synthesizer description		Page: 10	
AP-RADIOTELEFON %		Tegn. nr.:	75204-4E2

### Voltage controlled oscillator (75082-3E2)

The transistor Q 1 is used to switch between two loop filters. When Q 1 is 'ON' the slow filter R 1, R 3 and C 2 are in function while R 1, R 2 and C 1 give the loop a fast step response for Q 1 'OFF'. The fast loop filter is only used in connection with automatic channel scanning. Diode D 1 is used to clamp the control voltage thus preventing too great VCO frequency excursions when the loop is out of lock. The frequency of oscillator Q 2 is controlled by tuning diode D 2 while diode D 3 is for modulation. Transistors Q 3 to Q 7 make the three output buffers with ferrite core transformers L 3 to L 5.

### Synthesizer mixer (75019-3E2)

In the synthesizer mixer Q 1 is a 40 Mc oscillator with third overtone crystal X 1. This frequency is fed via L 1 to the mixer transistor Q 2. The VCO-signal goes through the dual gate Mos-transistor buffer Q 4 which gives high backward isolation but no amplification. Reaching the base of Q 2 the VCO-signal is mixed with the fourth harmonic of the 40 Mc to give an output signal of 3,2 - 5,2 Mc. DR 1 and DR 2 are part of a 10 Mc low-pass filter connected to the amplifier stage Q 3.

### Channel code

From the blockschematic of the Synthesizer circuit (Fig. 6) we have:

$$F_{VCO} = 4 F_x + N \times 0,025 \text{ Mc} \quad \text{where } 128 < N < 208.$$

- The VCO frequency lies 21,4 Mc above the receiver frequency leading to:

$$\text{Receiver frequency } F_m = 4 F_x + N \times 0,025 - 21,4 \text{ Mc (5).}$$

Here N is the division ratio and  $F_x$  is the synthesizer mixer crystal.

DIVISION RATIO AND CHANNELCODE

The division ratio N corresponds to the 8 - bit channel code in this way.

Bit number                                    8    7    6    5    4    3    2    1

Value of each bit                        128    64    32    16    8    4    2    1

Example: channel code =                1    1    0    0    0    0    0    1

N = 193                                    = 128 + 64 + 0 + 0 + 0 + 0 + 0 + 1

Logic 1 = +5 Volts. Logic 0 = 0 Volts

## Tuning instructions for AP 2000, 2 m

### 1. Tuning of the synthesizer circuit

#### A. Synthesizer oscillator

Connect a high input resistance DC-voltmeter to TP 1 on print board B 11. By tuning coil L 1 to max. a reading of approx. 3 V should be obtained. The coil L 2 is later used for frequency adjustment.

#### B. Phase locked loop

If the set contains more than one channel, turn the channel selector to a channel with frequency in the middle of the used band. Check the channel code with a voltmeter on points 1, 2 ..... 64, 128 on print board B 17. Computation of the channel code is contained in the technical description of the synthesizer circuit. Note that there are two types of VCO, one for the range 146-160 Mc and the other for RX-frequencies 160 - 174 Mc, and check that the right type is used for the desired frequency range. The marking is noted on the VCO-diagram. Connect the voltmeter to point 1 on the VCO print board and an oscilloscope (sensitivity 1 V/div.) to test point TP 1 on the logic print (print board B 17). Adjust the VCO trimmer until the loop goes in lock. The loop is in lock when a stable 25 kc ripple sawtooth is appearing on the scope, and the voltage on the voltmeter increases while turning the VCO trimmer clockwise. Adjust the VCO so that the loop voltage is 3 V. This loop voltage corresponds to min. 25 kc ripple on TP 1. For multi-channel sets, turn the channel selector to the lowest and highest frequency and check that the loop still goes in lock. Considering a set with the max. possible bandwidth 2 Mc, the loop voltage shall lie between 2 and 4 V going from the lowest channel to the highest in such a manner that

increasing voltage corresponds to increasing frequency.

C. RX-frequency

Select the mid-frequency channel and connect a 200 Mc counter to the VCO-output point 5. The reading will be RX frequency + 21,4 Mc and for fine tuning of the RX-frequency, use coil L 2 on synthesizer mixer print board B 11.

2. Tuning of the receiver

A. 21,4 Mc and 455 kc IF (print board B 01)

Connect a 21,4 Mc sweep generator (a 10,7 Mc sweep generator normally contains sufficient second harmonics to be used on 21,4 Mc) to point TP 1 on the RF and mixer print board B 08 and the (DC) probe on point TP 1 on the IF print board B 01. Adjust L 6 (print B 08) and L 1 (print B 01) for minimum ripple. L 2 is tuned to max. amplitude while L 3 is tuned to best possible symmetry. Use the lowest possible input level to prevent limiting in the second mixer. Connect the probe to the AF output from the detector (a suitable point is pin 1 on the ampl. print B 09) and adjust L 4 in the IF to max. discriminator slope and the best linearity.

B. RF amplifier and mixer (print Board B 08)

With the voltmeter on TP 2 (print board B 08) C 17 and C 18 are adjusted to max. deflection (approx. 1 V DC). With the signal generator connected to the receiver input C 2, C 3, C 6, C 9 and C 10 are now tuned to give optimum sensitivity.

C. AF-amplifier, squelch and key circuit (print board B 09)

Adjust the output level for the handset earpiece to 60 mV with potmeter R 31. (3,5 kc dev., 1 kc modulation.)

Alternative method for tuning of Rx front IF without  
a sweep generator

Adjust C 17 and C 18 as desired under 'B'. Connect the RF-signal generator output to TP 1 in the RF-amplifier and use the horizontal deflection voltage from an oscilloscope for modulation (FM) of the generator. Now the IF can be tuned as previously described. By connecting the signal generator output to the aerial input, all the capacitors in the RF-amplifier and mixer can be tuned to max. deflection with the probe on TP 1 in the IF amplifier.

3. Tuning of the transmitter

A. Transmitter mixer and amplifier (print board B 07)

The transmitter shall be keyed. The oscillator injection to the transmitter mixer is tuned with L i (print B 07) to max. DC-voltage on TP 1. Turn the capacitors C 2, C 6, C 11, C 13 and C 18 to max. capacitance. Connect the voltmeter to the can of transistor Q 2 (can is connected to emitter) and tune C 2 and C 6 to max. reading. Remove the cable from the transmitter-amplifier output (pin 4) and replace it with a wattmeter (50 ohms, range 1 W). Now tune C 11, C 13 and C 18 and readjust C 2 and C 6 to get max. output power (approx. 150 mW). When X-tal = 10,7 MHz, C24 is removed. When X-tal > 10,7 MHz, C22 is removed. When X-tal < 10,7 MHz, both capacitor are used.

B. 6 W PA-stage (print board B 06) or 25 W PA-stage (B79A)

Turn the potmeter R 1 (print board B 57 counter-clockwise to get the output power stabilization out of function. Connect a wattmeter (50 Ω, 10 or 50 W) to the test installation output and set the supply voltage to 12,0 V. Now tune all the trimmers in the PA-stage to max. output power and finish with a fine adjustment of C 18 on the transmitter amplifier print B 07.

C. Transmitter frequency

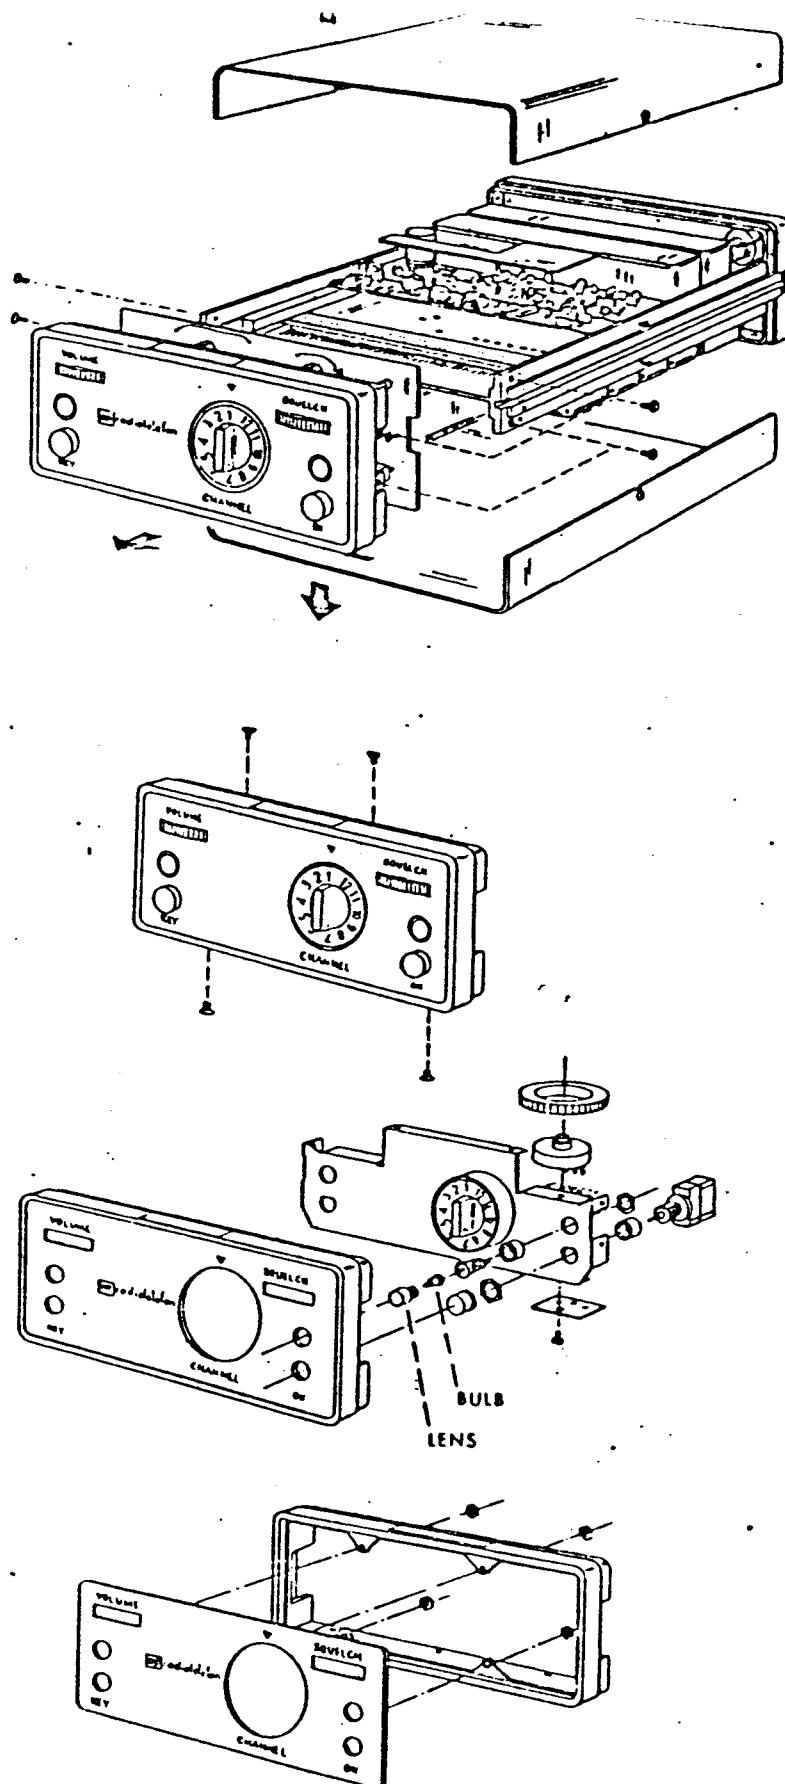

Connect a counter to the wattmeter and adjust the transmitter frequency with the capacitor C 29 in the Tx-oscillator print board B 11.

D. 25 W PA-stage (print board B 02-external)

Push the radio into the 25 W PA-stage, connect the wattmeter ( $50 \Omega$ , 25 W) and adjust C 1, C 2, C 5 and C 6 to maximum output power with a supply voltage of 12,0 V. Increase the supply voltage to 13,6 V and turn the potmeter R 1 clockwise until the output power decreases to 25 W. Check the power regulation by supply voltages lower than 13,6 V, the output power may be a little less than 25 W but for tensions from 13,6 V and up the output power shall be held constant on 25 W.

E. Modulation amplifier (print board B 10)

Connect a modulation meter to the transmitter and a tone generator to the microphone input 1. The generator must have a low output impedance. Turn the 3 potentiometers to centre position and set the generator to 1000 Hz. With an input level of 20 mV, potmeter R 27 is adjusted to give  $\pm 5$  kHz deviation on the modulation meter. Decrease the input level to 1 mV and adjust potmeter R 3 to a deviation of  $\pm 3$  kHz. Repeat the procedure to check and fine adjust R 27 and R 3 if necessary. If the station is equipped with a handset, R 27 is adjusted to  $\pm 5$  kHz with an input level (1000Hz) of 2 V. When the level is decreased to 200 mV R 28 is set to give a deviation of  $\pm 3$  kHz.

Ved underliggende VCO udregnes x-taller og frekvenser således:

VCO-frekvensen  $F_{VCO}$  udregnes efter:

$$F_{VCO} = F_{Rx} - 21,4 \text{ MHz}$$

Synthesemixerkrystaller udregnes efter:

$$F_x = \frac{F_{Rx} - (N \times 0,025)}{3} - 21,4 \quad 25 \text{ kHz kanalafstand}$$

Deleforholdet N er da:

$$N = \frac{F_{Rx} - 3 F_x + 21,4}{0,025}$$

$$\text{hvor } 3F_x + N \times 0,025 = F_{VCO}$$

Senderblanderkrystal ap 22:

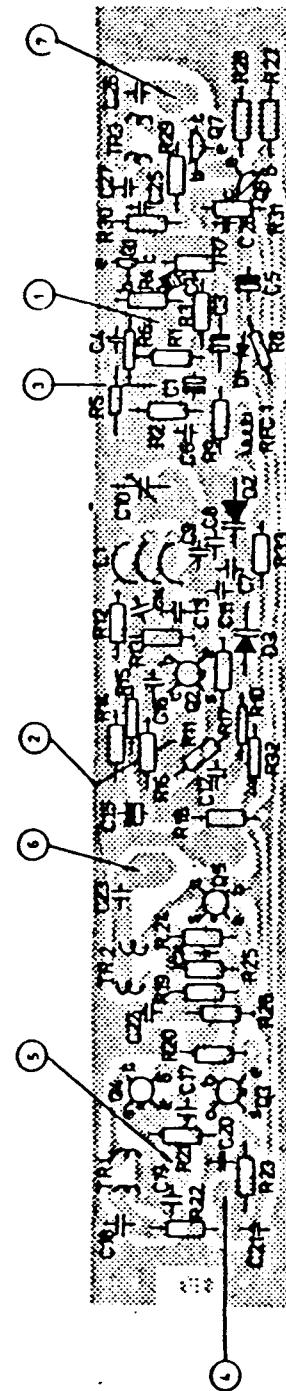

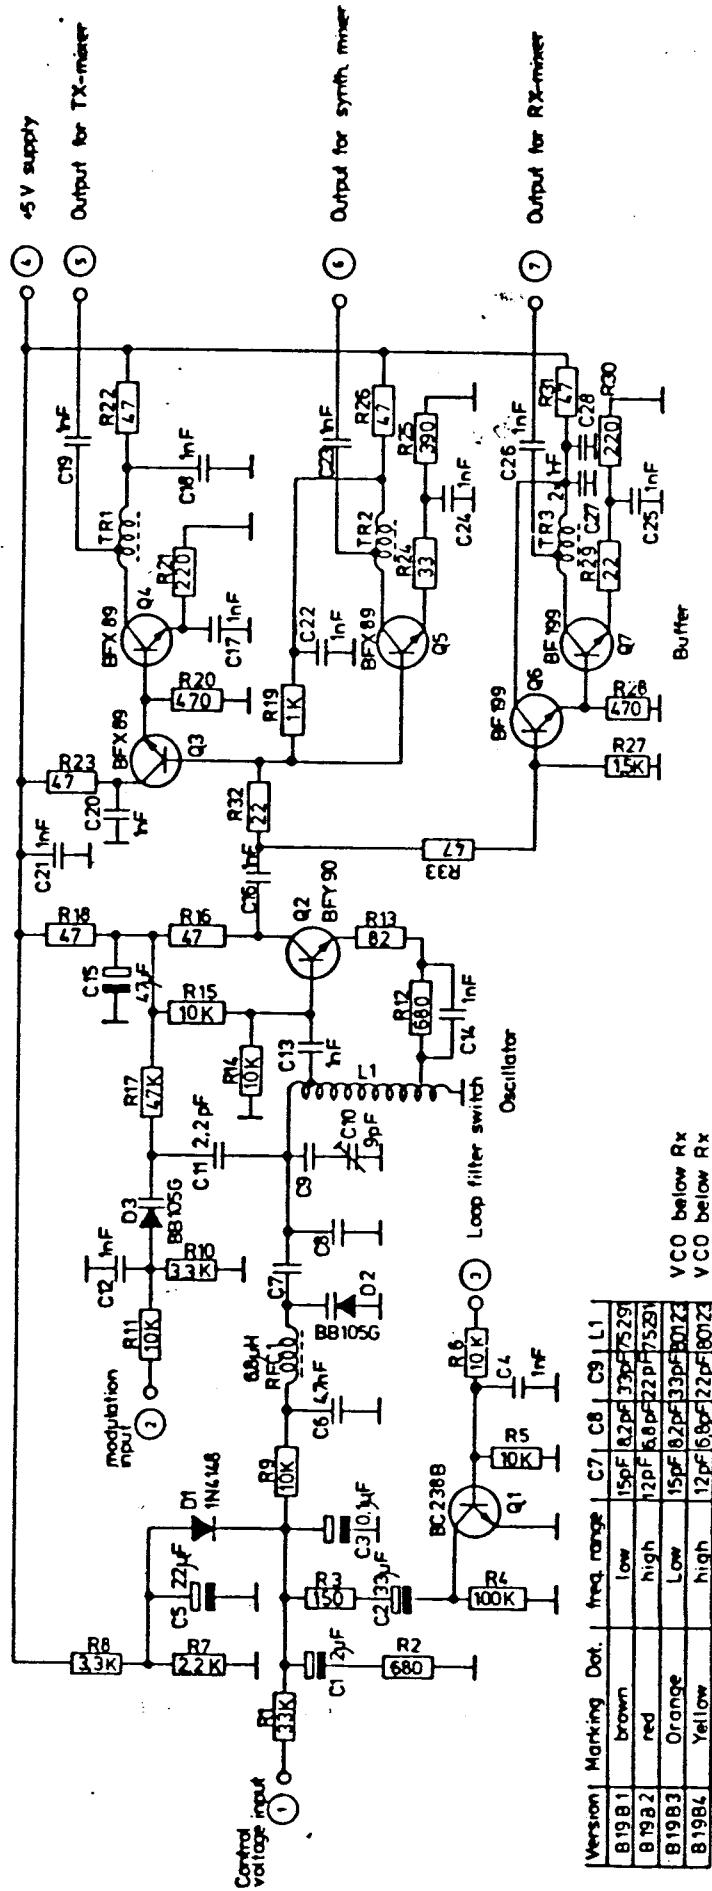

$$F_x = \frac{F_{Tx} - F_{Rx} + 21,4}{2}$$

Med venlig hilsen

Lars Buus

<b>Stromforsyning for bæretaske</b> <b>218-050</b>		

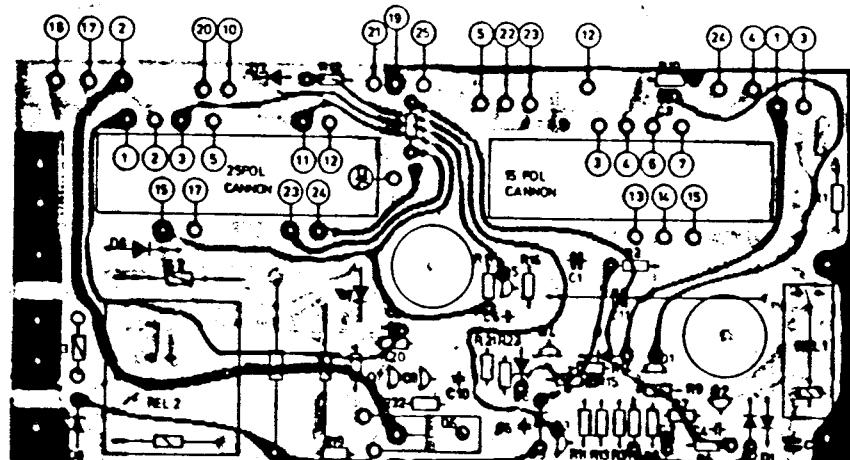

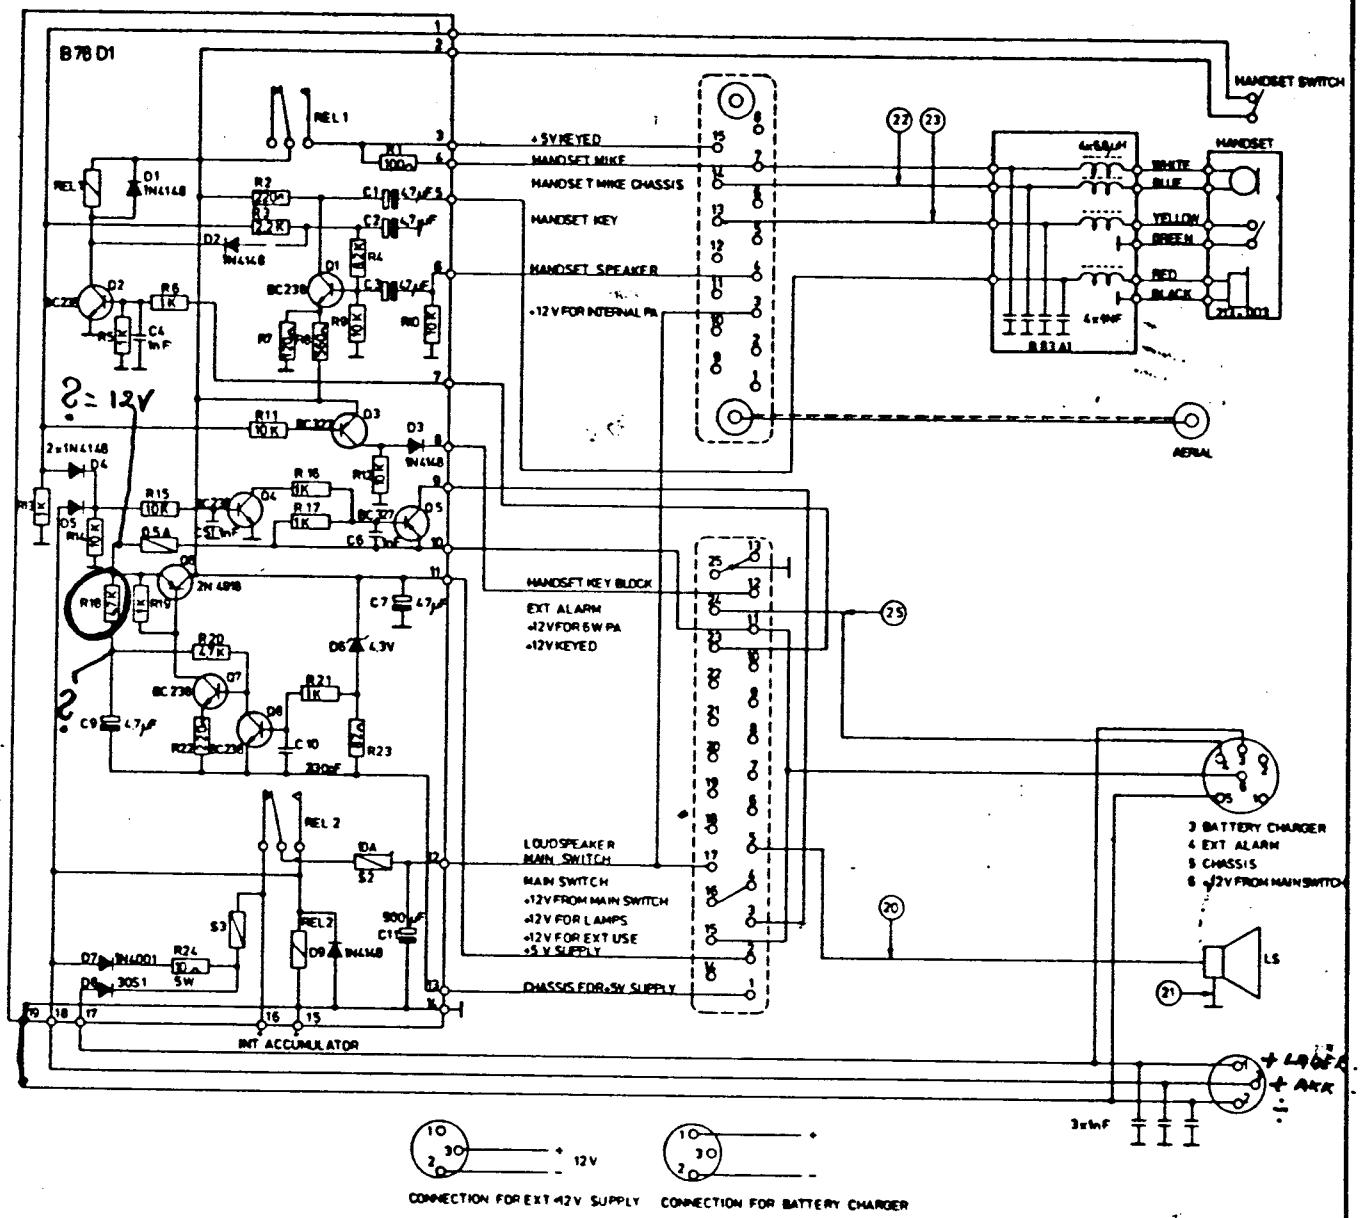

## Strømforsyning 218-050

Data for strømforsyning før bæretaske:

Input spænding	: 200 - 240 V 50 Hz
Input strøm	: Max. 1 A
Output spænding	: 12 - 13 V DC
Output strøm	: Max. 10 A
Max. temperatur på kasse	: 90° C
Max. belastning	: 10 A i et minut og 1 A i fem min.
Middel strøm ved 25° C og 220 V	: 3,5 A.
